THEORIES ON POPULATION

Demographic studies form the most fundamental aspect of human geographic study. In the demographic analysis different human geographers attempted the development of population theories to outline the causes & consequences of growth of population. Among the major examples of population theories :=

<i> Malthusian Concept

<ii> Marxian Concept

<iii> Demographic transition model, are included.

1. MALTHUSIAN CONCEPT

English demographer Robert Thomas Malthus propounded first demographic theory oriented towards urgency of controlling population way back in 1789. His concept published in the text entitled "Theory on Population" emphasized upon two universal laws, regulating human existence worldwide irrespective of cultural

Facebook Group: Indian Administrative Service (Raz Kr)

identities or economic levels of development. These include:

- Persisting pattern b/w the sexes
> Food required for survival.

As per him, under the effect of first law, early marriages, which facilitate longer marital bondage in the reproductive age, are leading to possibility of larger number of births. While analysing this cascading interrelation he do mentions preventive checks which are defined to be the control measures regulated by human population. In this category, he included delay of marriage, moral restraint and abortions as the possible ways. Failing to apply preventive checks will make uncontrol growth of population. The rate of increase of such uncontrolled population have been recognised to be geometric, compared to which, the rate of increase of resource base will be arithmetic. It is this difference in rates that in due course of time will

generate demand-supply mismatch leading to the division of the society into : the haves (rich) & the have nots (that are poor). Moreover, generated demand-supply mismatch will create such magnitude of deprivation that nature-induced positive checks comes into effect. In this category - starvation, epidemics and even scarcity-induced wars are included. In the influence of positive checks, nature re-balances population & resource base.

* This simple descriptive approach of Malthus is identified to be important contribution as this marked the beginning of theory-building tradition in social sciences. Moreover, it projected the urgency of controlling the population. Added to these, Malthusian concept sustains its practical validity in the fact that all anti-natalist population policies involve common element of delaying legal age of marriage.

limitations:

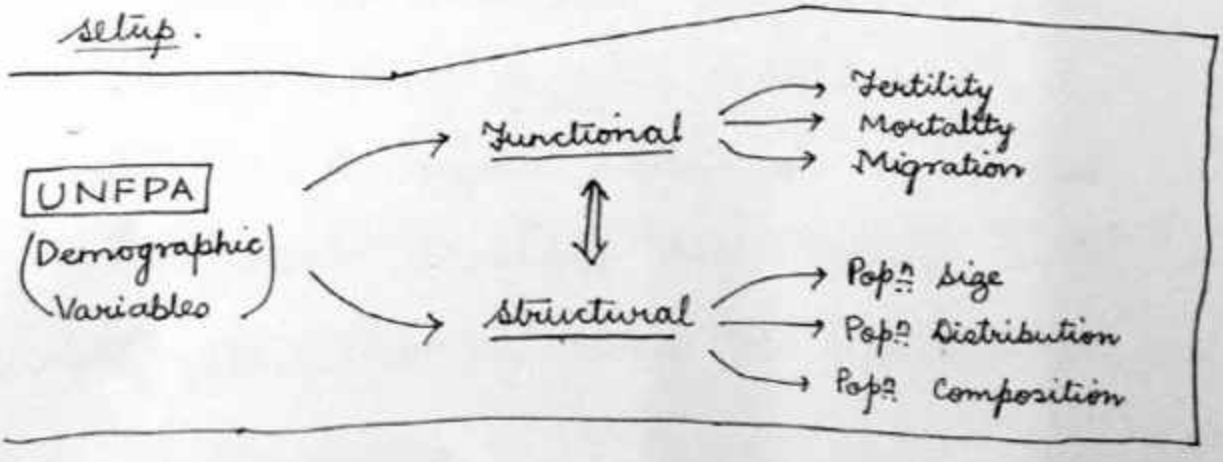

the Malthusian approach also incorporate quite strong share of criticism which is largely categorised on technological terms, sociological parameters and economic terms. Technologically, every exponential growth of global population have been simultaneous to major technological innovations, so much so, that booming growth of global population since 1950s have been simultaneous to termination of starvation related deaths. This justifies that the ratio analysed in the theory are highly impractical though there is the urgency of controlling the population — the approach called Neo-Malthusian. Sociologically, the theory is criticised not just in reg ignoring biological limit of fertility but also generalising biological need of having sex with sociological need of giving birth to a child. This generalised combination is being applied by the scholar scholar to justify his theory of urgent requirement of controlling fertility. On economic front, strongest word of criticism relates to Karl Marx,

who discarded the conclusions drawn in the theory that growth of population leads to the division of society. He emphasized that divided society leads to the increase in population.

B. MARXIAN CONCEPT

Karl Marx, retaliating to Malthusian demographic theory, outlined few of the conclusions on population, refereed to as Marxian concept on demography. Marx identified that it is not the growth of population but evils of capitalism that makes the society divided into rich and poor. The rich are the owners of means of production and therefore, not just controls entire production mechanism & process but also completely acquires the positive difference between input cost and sales realisation i.e. profit. Moreover due to capitalist setup of functioning, rich also saves on the labour wages. It is therefore that limited rich population keeps on multiplying the asset, i.e. money, they possess.

In comparision, the poor who represent the work force in the production process are not just being subjected to long hours of working but are also deprived of the basic wages, making them live in absolute poverty. It is this condition that makes them multiply the assest, that is population, they posses; with the perception of increasing workforce & thus overall income levels of the family, causing population increase. Analysing this inter-relation, Marx strongly advocated that as the cause of population increase is economic, population can be controlled only by generating more fair and equitable economic setup as socialist setup.

C. DEMOGRAPHIC TRANSITION MODEL

This model or VITAL REVOLUTION forms one of the most utilised, analysed and manipulated demographic model. This model takes into consideration temporal transition of fertility and mortality, thus, total population in any given area. This model was propounded by Thompson (1929) and Notestien (1945) Based on demographic experience of European countries, this model, incorporates 3 well-defined assumptions:=

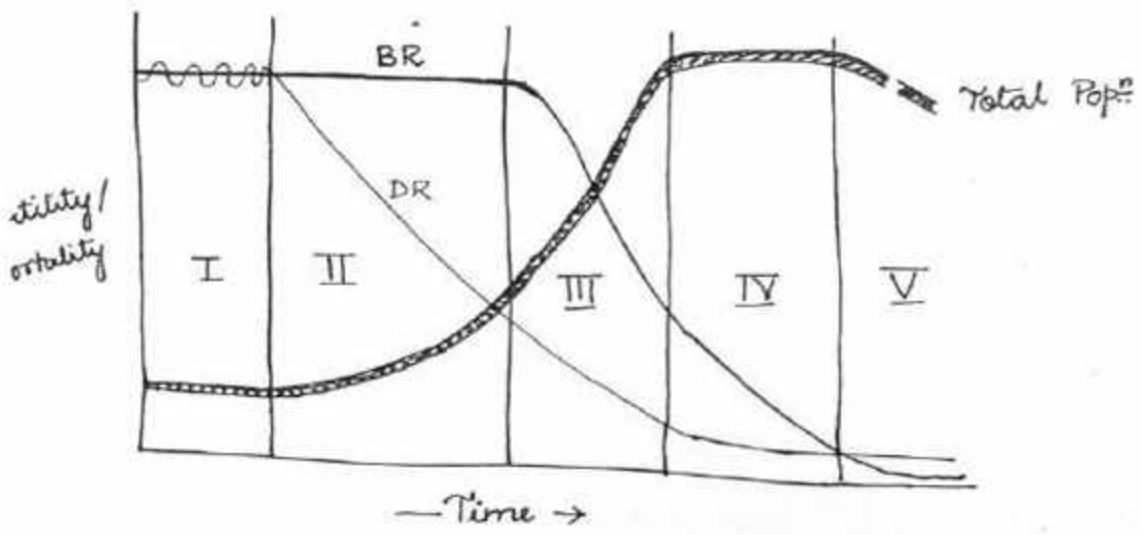

(i) Both fertility and mortality changes from high levels to low levels in the regular temporal sequence.

(ii) Decline in mortality is registered much prior to decline in fertility.

(iii) This transition from high rate to low rate also involves transition in socio-economic setup of the country.

The original developed model divided the model into 3 different parts called stagal transition, causative components & predictive elements.

n year 1970, Peter Haggett incorporated predictive component to the stagal transition making the theory involving 5 stages, different from original 3 stages.

I : High stationary phase — Fourth World Community

II : Early expanding } — Almost all Africa
II : Late Expanding } — Almost all Asia & L. America

IV : Low stationary } Developed
V : Declining stage } Continents

Crude Birth Rate
Crude Death Rate
Total fertility rate
Natural Increase = $\left\{\frac{(BR - DR)}{1000} \times 100\right\}$ %

STAGE I

It is high stationary or early european. This demographic stage corresponds to high fertility with fluctuating high mortality. The prevailing high mortality corresponds to lower life-expectancy and higher infant mortality rate (number of deaths of infants (0-1 years) per thousand live births per year). In this demographic stage, total population remains stationary. This stage is being experienced, largely by primitive 4th world communities in present scenario.

STAGE II

early expanding stage or industrial european stage. This stage marked its beginning with beginning in decline in mortality due to the advanced medical support system. Continuously decreasing mortality combined with constant high fertility makes this stage represent growth of population. With growth rate increasing with subsequent temporal developments i.e. increasing gap b/w declining mortality and static high fertility, it is end of

this stage that population explosion is correlated. This stage is being experienced by almost all the African countries along with Afghanistan and Yemen as Asian representatives. As per crude birth rate (no. of live births per 1000 popⁿ per year) which is 27 as global average (as per 2010-11 UN population table), most of the recognised countries have high crude BR i.e. >40 live birth per 1000 per year with Afghanistan, Niger and Somalia having crude birth rate of 50 live birth. In the absence of comparable studies supported by crude death rate (no. of deaths / 1000 popⁿ / year) in global perspective, it is the data table of total fertility rate (avg. no. of children given birth to by a female during her reproductive age) is taken into consideration. Combined with death rate, total fertility rate identifies replacement levels of population in b/w 2.1 to 2.5. The global total fertility rate is 3.3 with most of the recognised

countries having total fertility >4·5 justifying early expanding stage being experienced by them.

STAGE III

Late expanding or modern European stage. This stage represents beginning of decline in fertility rate which marks continuation in the growth of population but there is continuous decrease in the growth rate of population. This stage is experienced by most of Asian, L. American along with northern African countries with S. Africa. As per 2010-11 data tables, all these regions are not just having moderate levels of crude birth rate (20 to 40 live births) but also represents total fertility rate in the range of 2·5 to 4·5 depicting growing population but with stability.

STAGE IV

Low stationary stage. This stage represents lower levels of both fertility and mortality making total population either completely stable or near stability. This stage was outlined in predictive

element in the original model. It is being experienced not just by developed new world which started their demographic cycle slightly later than European countries but also successful anti-natalist countries which completely skipped one of the stages of demographic cycle. China, Kazakhstan (Kajaktan), Turkey and Uruguay forms the examples. In all the refered countries crude birth rate of <20 & total fertility rate at or near replacement is outlined as per 2010-11 UN population tables.

STAGE V

Declining population stage. It was also included in predictive component in the original model. In this stage, declining fertility declines below mortality, making total population decline. This transitional stage is experienced by most of the European countries which have total fertility rate below replacement (1.8 or less), justifying the threat of depopulation. This characteristics of European countries depicts the conclusion of the

Facebook Group: Indian Administrative Service (Raz Kr)

demographic cycles as these countries mark the earliest beginning of demographic transition.

CAUSATIVE COMPONENTS :

The causative components outlined by the propounders of demographic transition model denotes the attempt to explain the reasons of different countries experiencing different stages of demographic transition. The best identified conclusions are credited to Thewarlta and Chung who have identified dual-characteristics of man - "biological" and "cultural". Biologically human character reveals similar pattern in global dimension. However, culturally there is major difference regulating fertility and mortality patterns. In the cultural dimension, economic growth is also of prominent significance as economic development is formally recognised to be the most effective contraception.

GROWTH & DISTRIBUTION : GLOBAL POPLN

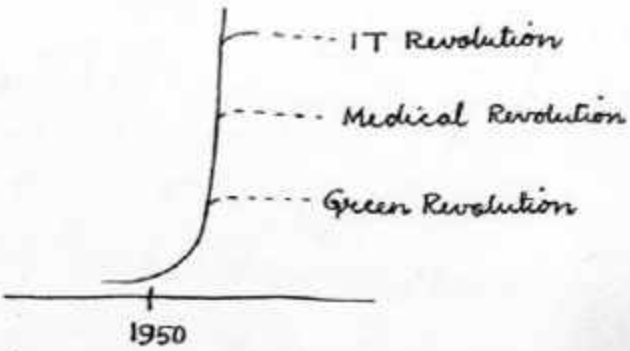

The beginning of culture is traced back from 10000 years before present which represents the time of completion of evolution of homo sapiens and beginning of paleolithic culture. It is since 10000 years before present that the interpretation of human population growth is also taken into account. Practically for the lengthiest temporal sequence i.e. 10000 years before present to upto 1750s, global population remained at constant level depicting stage I of demographic transition. Since 1750s to 1950s, minor increase in population representing the beginning of second stage of demographic transition is outlined. It is since 1950s that exponential increase in the global population represents the growth trend to be J-CURVE. Analysis of population growth combined with growth in the technological capacities makes the temporal analysis representing S-CURVE. The S-Curve denotes

Facebook Group: Indian Administrative Service (Raz Kr)

that every level of exponential population increase is both the cause & effect of technological innovations. This is also recognised as homeostatic plateau or Neo-Malthusian Approach with at least three well-demarcated S-Curves since 1950s, representing green revolution, medical revolution & IT revolution.

J-CURVE

'S'-Curve / Homeostatic Plateau

NEO-MALTHUSIAN APPROACH

In accordance to UN population tables 2010-11, the global population have reached slightly over 7 billion mark and is still growing at the rate of 260000 live births per day. As per this, projected year of global population stability is 2150. By that time levels of global population will be near 11 billion. More than 95% of this projected

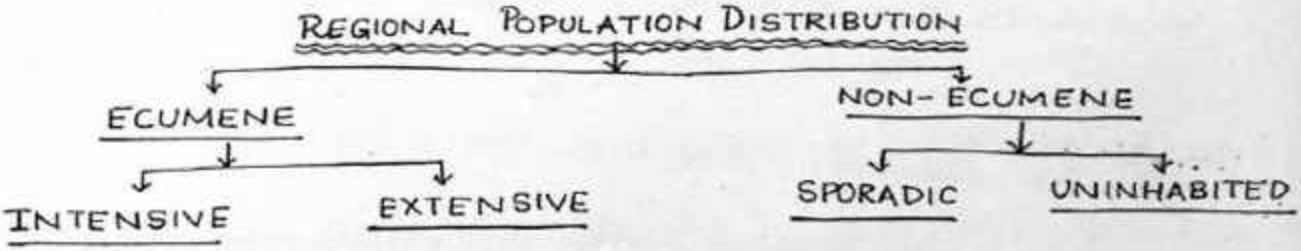

increase is likely to remain confined in Africa followed on by south Asia.

The analysis of population pattern i.e. distribution readily reveals that like diverse characteristics of physical attributes of planet Earth, population distribution is also highly diverse. The parameters of distribution analysis justifies that more than 75% of the global population is confined in less than 10% geographical area. Moreover, near 30% of geographical stretch represents to be absolute uninhabited. In terms of total population, unequal distribution is justified with the fact that only 10 countries of the world accounts for >60% of global population including China, India, USA, Indonesia, Brazil, Pakistan, Bangladesh, Japan, Russia and Nigeria. This list of most populous countries have maxm representation of Asia which is recognised to be top ranking ever in the density distribution. The 2010-11 UN population

table identifies average global population density to be 41 persons per sq. km. It is continents of Asia (108 person / sq. km) and Europe (101 persons/sq.km that forms dense clustered continents whereas Africa (21 persons/sq. km), Latin America (20 person/sq km), Anglo-America (14 person/sq. km.) and Oceania (3 person per sq. km.) represent sparsely clustered continents Much elaborate analysis of density distribution of population involves regional parameters which divide the habited world into Ecumene and Non-Ecumene locations.

Anglo-America ⇒ Only USA & Canada

Mexico + S. America ⇒ Latin America

Rural area – Extensive land use.

Urban area – Intensive land use (Vertical dimension)
↓
Sky Scrapers
Multi-storys

ECUMENE

the ecumene region in the present density profile is identified to be areas with more than 100 persons/sq km of population density. In this category, 4 well-defined regions of world are included :-

East Asia

South Asia

Eⁿ Anglo America

Wⁿ Europe.

Both East and South Asia represents dominant rural agrarian setup forming examples of extensive ecumene including China, India, Pakistan and Bangladesh. In comparision both Anglo-American (along Great Lake region) and European (northern European plains) as well as Japan represents industrial urban characteristics forming examples of intensive ecumene.

ON-ECUMENE :

At the absolute other end non-ecumene regions represents the regions with population density of < 10 persons per sq. km. In this category, unfavourable locations as Equatorial Rain Forest, Tropical

desert, tall mountains & polar desert are included. It is within these regions that benefitting from variable set of favourable determiners that sporadic ecumene adds to the dimension of regional population distribution. Regulated by fertile soil, generation of sporadic extensive ecumene includes Java Islands, Mekong delta, Mesopotamia, Tuscarian Plains.

In reference to favourable resource base including mineral resources, energy resources or marine link resources — big range of sporadic intensive ecumene regions exist. Among the prominent examples Kiruna (iron-ore, Sweden), Magadan (coal, Siberia), Manaus (gold, Brazil), Namib Desert (uranium, Namibia) are included: for mineral resource category. In the energy resource: Persian Gulf shoreline (crude oil), Sakhlaine (crude oil, natural gas) makes most prominent examples. In the marine links, Honolulu, Hawaiian Islands, Singapore representing port of Call along with Port Said, Port Suez, Panama City, Colon, represent excellent examples.

the development of sporadic intensive ecumene is also correlated to favourable habitat with almost all the megacities of African Savannah as Adi. Ababa, Kampala, Nairobi being located at the elevation of >3000 m. In the similar category, administrative capital of Yemen – Sana and administrative capital of Bolivia – Lapaz (also the beneficiary of highest navigable lake L. Titicaca) are also included. Rest of the world is incorporated in moderate ecumene characteristics between the two extremes.

POPULATION COMPOSITION :=

The demographic structural variable called population composition takes into consideration age and sex composition of population which is not just determined by functional demographic variable as fertility, mortality and migration but is also correlated to determining role of these functional variables. The analysis of population

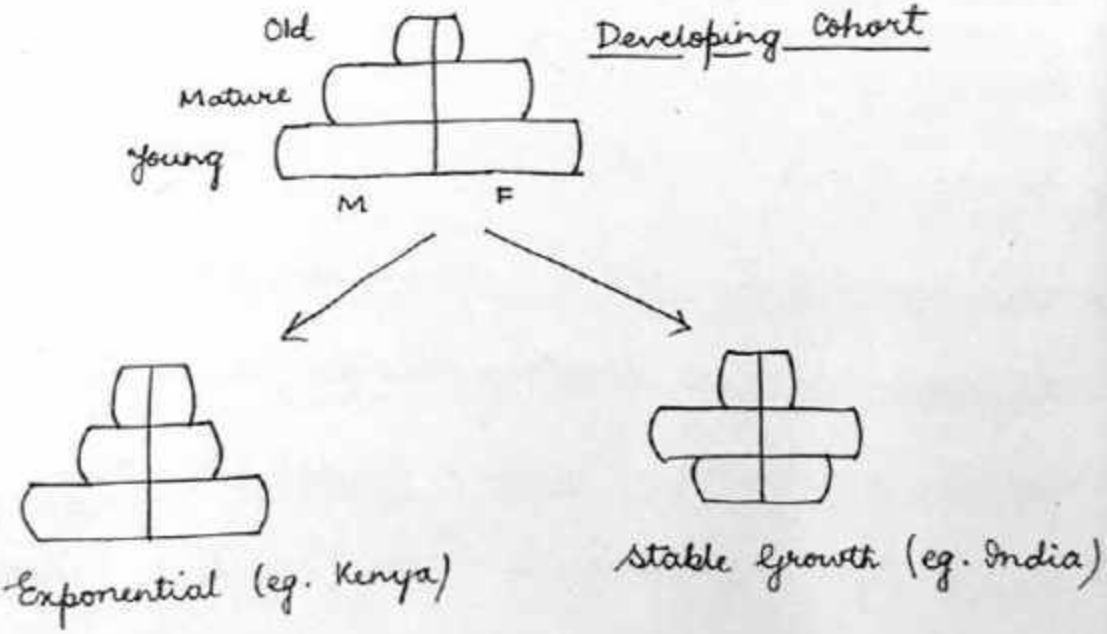

composition marked its formal beginning with the development of graphical device called <u>age-sex pyramid</u> in the beginning of 19th century. This graphical device incorporate three age groups - <u>young</u>, <u>mature</u> & <u>old</u> in the vertical alignment with male & female population demarcated on horizontal alignment. Since 1800, variable pattern of population profile resulted in the development of variable shapes of age-sex pyramid. It is in accordance that the graphical device is more commonly referred to as <u>COHORTS</u> i.e. age-sex groupings. Generally the cohorts on the map of the world represent 2 well-defined categories :=

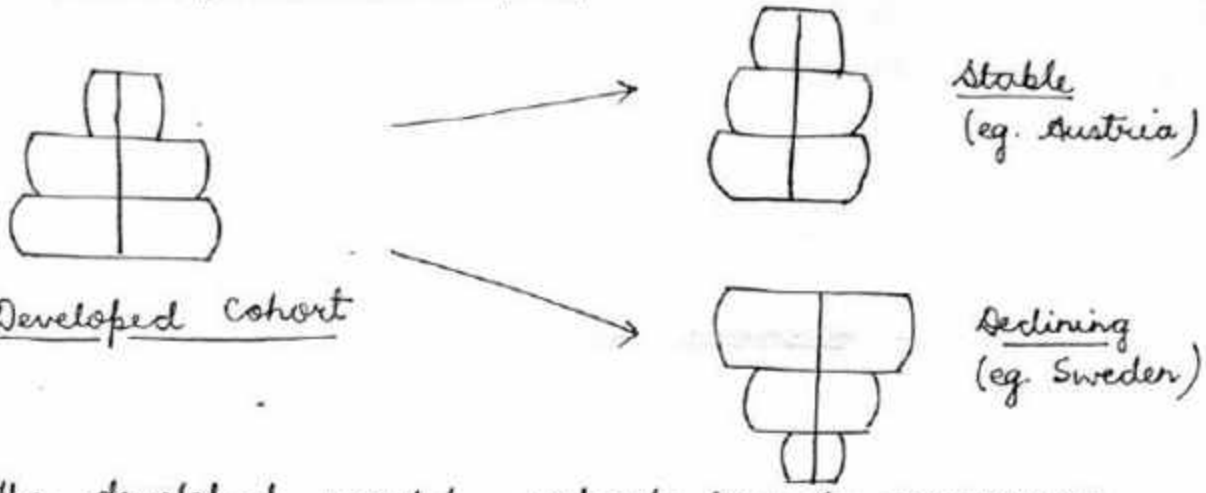

(i) Developing world cohort

(ii) Developed world cohort

The <u>developing world cohort</u> largely depicts <u>broader profile</u> denoting larger share of global population, <u>shorter height</u> depicting lesser life-expectancy & also involves <u>lesser</u>

female population in the old age cohort compared to the male counterpart. Within this category exponential growing population and stable growing population are absolutely distinguished. The exponential growth cohort as of Kenya is true-pyramid with broad base & narrow apex depicting high fertility rates. In comparision, the cohort of growth with stability as of India have mid-age cohort swoller (broader) depicting significant control in fertility rates, thus, growth rate of population, though population is still growing.

The developed world cohort reveals narrower profile depicting lesser share of global population, are significantly tall representing higher life-expectancy Moreover, females outnumber the male counterpart in old age cohort representing the fact that females are less prone to old age diseases. Even in this category, 2 well-defined sub-divisions can be outlined: Stable population & declining population.

The stable population cohort incorporates near absolute balance of population in all age cohorts. This is best recognised with Austria. In comparision, the declining population represents inverted pyramid with largest population share in old age cohort. Sweden is the best representative. It is the analysis of population composition that helps in analysing the

Facebook Group: Indian Administrative Service (Raz Kr)

ature of demographic dividends i.e. workforce, dependency ratio i.e. old and young age cohort along with prevailing nature of gender inequality.

POPLN PROBLEMS & POLICIES

Population size when is analysed in context of carrying capacity of the location, demographic problems / challenges get highlighted. The carrying capacity of a given location is determined by mobilised resource base which in-turn is depended on mobilised technological capacities. The nature of problem can also be specified in the reference to desired levels of living by any given location. Taking all these dynamic components into consideration, global population problems and related policies are classified into 2 categories:-

(A) Over-population with anti-natalism

(B) Under-population with pro-natalism.

Facebook Group: Indian Administrative Service (Raz Kr)

Facebook Group: Indian Administrative Service (Raz Kr)

A. OVER POPULATION :

Overpopulation represents the demographic challenge with population more than mobilised resource base. This type of population problem apart from depicting the consumption of entire growth benefit also correlates to variable magnitude of deprivation. more workforce less work as important dimension of problems. This demographic challenge is identified to be global in nature., with almost all the developing continents suffering from this challenge. Mobilisation of policies to minimise the impact of this challenge is called anti-natalism. It is the population policy that is oriented towards controlling the birth rate. The nature of anti-natalism implied in global perspective includes:

(i) KAP Anti-natalism

(ii) Indian "

(iii) Chinese "

Facebook Group: Indian Administrative Service (Raz Kr)

Facebook Group: Indian Administrative Service (Raz Kr)

The KAP anti-natalism i.e. knowledge, application and practice was the ambitious beginning attempted by UN in beginning of 1950s involving developed countries. Orientation of this oldest anti-natalism was to apply the knowledge of family planning possessed by developed world to the developing world which were projected with exponential increase of population in the likely future. This ambitious program proved out to be a complete failure not just because the nature of program was highly academic with complete lack of spicified targets but also prevailing disbrust among the newly independent countries for the extended support by "ex-colonial countries".

Facebook Group: Indian Administrative Service (Raz Kr)

Lecture 54

Date 14/04/2014

INDIAN

The second most populous country of the world, India marked the beginning of explicit national popln policy oriented towards controlling birth way back in 1952. Indian anti-natalism incorporate very well-defined temporal phases of modifications in the sequence of realisation with its implementation. The demarcated phases include:

Voluntary phase

Family welfare phase &

Contemporary phase

The first phase of anti-natalism of India remained prevalent in between 1952 to 1972. This phase of anti natalism is recognised to be absolute example of voluntary phase implemented on the grounds of absolute choice of the recepient. This voluntary phase also incorporated informative clause that is

Facebook Group: Indian Administrative Service (Raz Kr)

nforming the individuals about the benefits of small family & the possible ways of controlling the family size. This phase involved the development of health services network as the fundamental infrastructure reqd for the success of population policies were missing in the country. Near 20 years of implementation statistically this phase of anti-natalism proved to be a failure with India touching highest decadle growth rate of population ~24% in 1971 census, which corresponds to population explosion experienced in the country. With 71 data-tables released Indian anti-natalism was moulded to second phase involving family welfare. Based on the realisation that in democratic setup voluntary clauses of implementation of policy cannot be molded and that if parents are assured of healthy survival of their kids, they will adapt

Facebook Group: Indian Administrative Service (Raz Kr)

to the small family norms. Family planning was made family welfare in the country. In this phase of anti-natalism pre- & post- natal health services was strongly enlarged and there was the beginning of countrywide immunisation programs. This phase readily marked the success as 1981 census, referred to as watershed census year made India enter the third stage of demographic transition i.e. beginning of decline in the fertility rate. This success however was simultaneous to the realisation on <u>regional</u> disparity prevailing in the country. Indian demographic transition as growth with stability evolved an absolute divide between peninsular and extra-peninsular regions. Most of the peninsular states readily responded to family welfare anti-natalism but the then <u>bimaru</u> states mainly including hindi heartland

uled to generate desired transition. Poor societal 'alus of females; lack of education, wedespread isconceptions, Strong desire for male child formed : major points of realisation of non-response. king this into account in year 2000, India broduced the contemporary phase of population slicy which continued with voluntary clause, amily welfare clause & was added with ducation, girl and women empowerment as ddilional clauses. This contemporary phase epresents its success with the fact that the ensus decade (2001-2011) is the only census 'ecade that marked the beginning of articipation of Empowered Action Groups (EAG) lates registering beginning of decline in the 'erlility rate. The contemporary phase also ncludes initiation of clauses of Appeasements

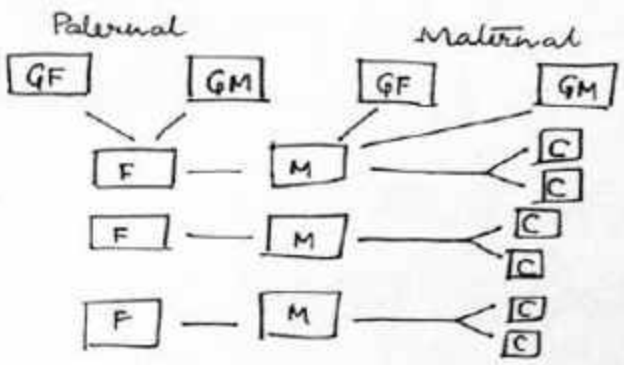

involving medical insurance to the couples below poverty line with 2 children along with recognition & provision of awards. For panchayati Raj institutions in mobilising small family norms. Indian anti-natalism in all its dimensions justifies to be the example of slow but steady successful anti-natalist country.

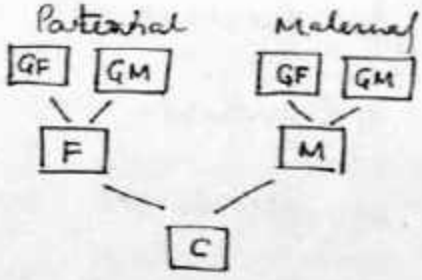

CHINESE ANTI-NATALISM

China forms the youngest example of anti-natalist demographic overlation marking beginning in 1982. Following Maoist population policy i.e. pro-natalism China multiplied the population to become the most populous country of the world immediate after attainment of independence - Based on the realisations of consumption of economic benefit with ever increasing population, China moulded Maoist population policy to anti-natalism with

mendment to the constitution making one child
family — a compulsion to be followed. In
irst 20 yrs of implementation China attained
population growth in year 2000. This cascading
uccess is attributed to the fact that in
mplementation of anti-natalism there was
omplete termination of individual's independence
n deciding the time & size of the family.
fficient network of primary health centres,
ept monitoring network & series of economic
anctions for individuals or families facilitated
the success. Success of Chinese anti-natalism
lso generated wide range of criticism both
n economic and ethic grounds. Economically,
here is a huge projected scarcity of workforce
n China in coming few decades. Ethnically,
minorities like Tibetans always discarded to
accept the rigid clauses of anti-natalism.

In addition China has evolved as poorest sex ratio from among the populous countries of the world as adverse outcome. In year 2000, therefore, China slightly molded its anti-natalism by permitting ethnic minorities to have two children per family reviving the growth rate that is at 5% per decade as per 2010-11 UN population table (in India, decadle growth rate is 17% per ~~day~~ decade).

UNDER-POPULATION

This population problem correlates to lack of available of human resource base reqd. to mobilise or sustain economic growth and infrastructure This population problem have projected in continent of Europe which reveal the examples of completing or being at the verge of completion of demographic cycle. Old age cohort involves maximum population with fertility rates below replacement levels. This makes most of the European countries not just suffering from the threat of depopulation but also to tremendous scarcity of work force with 9/10 individuals in most of the European Countries to be pensioners by 2014-15. Based on the projections of the threat of depopulation European Countries marked the beginning of pro-natalism way back in 1960. Pro-natalism is the population policy that encourages higher fertility levels. The first phase of pro-natalism traced back to the decade

of 1960s was oriented towards terminating individuals independence with implementation of clauses as making abortions illegal. It was not just the failure in attaining the desired results but also criticism that since mid 70s pro-natalism in almost all the European countries has not just been made voluntary but includes excessive dimensions of appeasements. The extreme-most case in this category is French population policy which involves provisions of appeasements to generate young & large families including moulding the town-planning so as to generate neighbourhood facility for infants & young kids, flexible working hours for the parents of infants & young kids along with extensive maternity & paternity leaves with full salaries with provisions of increase of leave with successive births. Even with these clauses pro-natalism have proved to be a

ziture population policy making even a country ike Germany to ease the visa norms so as to ttract quality work-force from around the orld.

GROWTH & DISTRIBUTION OF INDIA POPLN

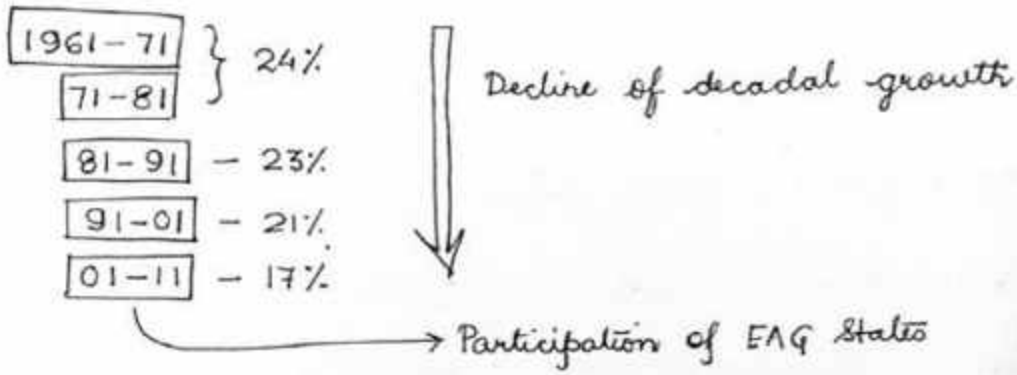

ronologically growth of Indian population is ell outlined into 4 different phases since the ginning of 20th century.

a) High Stationary Stage
b) Slow growth stage
c) Exponential growth stage
d) Growth with stability.

The high stationary stage was experienced in India between 1901-21 census years. High fertility combined with high mortality represented this stage 1921 census identified as watershed census year involving significant reduction in mortality rates paved way to slow growth stage. This stage was extensive between 21-51 census years

continuously declining mortality combined with exponentially high fertility resulted in continuous increase in the decadal growth rate of population. Post independence b/w 1951 and 1981 censuses, India experienced exponential population growth; reaching highest on records decadal growth rate of population : 24%. Since 1981, the second watershed census year, with India entering stage III of demographic transition growth rate of population started declining with beginning of control of fertility. This phase called phase of growth with stability have continued even in the last census decade registering ~17% of decadal growth rate. 2011 census also identifies that this decadal growth rate have been attained with the first time participation of EAG states which collectively accounts for ~46% of the country's population. Combining it with UN population tables, Indian decadal growth rate

till continues to be third highest (Nigeria - 26% & kistan - 24%.) and is considerably higher than te global levels of 12% justifying that India is ll set to become most populous country of the orld in coming decade.

he distribution of population in the country oth in terms of total population and density distribution reveals unequal pattern. The total opulation of India that is accounting for 17.5% of the global population is the combined population of USA (Rank : 3rd), Indonesia (4th rank), Brazil 5th Rank), Pakistan (6th rank), Bangladesh (7th rank), Japan (10th rank).

This gigantic population to the tune of >50% is confined only in 6 states of the country:

Facebook Group: Indian Administrative Service (Raz Kr)

U.P (population more than Brazil), Maharashtra, Bihar, WB, AP and MP.

The distribution characteristics involving complete map of world, however, correlate to density distribution. Indian avg. population density is 382 persons/sq. km as per 2011 census. In regional parameter density distribution divides the country into 3 well-defined categories:

(i) Dense clustered regions.
(ii) Sparse " "
(iii) Moderate " "

The Dense Clustered Regions with population density of more than national average includes all the UTs including NCT, except A&N Islands. Commonly for all UTs, small geographic size makes the primary cause of heavy population load. Specifically N.Capital 11000 persons/sq. km, Chandigarh - 9000 persons/sq km. involves the commercial & administrative attractiveness as the additional cause of such exponential population density.

Facebook Group: Indian Administrative Service (Raz Kr)

U.P (population more than Brazil), Maharashtra, Bihar, WB, A.P and M.P.

The distribution characteristics involving complete map of world, however, correlate to density distribution. Indian avg. population density is 382 persons/sq. km as per 2011 census. In regional parameter density distribution divides the country into 3 well-defined categories:

Commonly for all UTs, small geographic size makes the primary cause of heavy population load. Specifically N.Capital 11000 persons/sq. km, Chandigarh - 9000 persons/sq km. involves the commercial & administrative attractiveness as the additional cause of such exponential population density.

Facebook Group: Indian Administrative Service (Raz Kr)

or Puducherry, Lakshadweep, Daman & Diu: popln
lensity of >2000 persons reveals economic
ılbradweness as prominent additional cause. For
adar & Nagar Haveli, therefore, it is only small
ıze combined - with large population that depicts
re population density at near 700 persons/sq. km.

From among the states,
ihar (1100 persons/sq. km) - most densely clustered
lale & U.P. represent heavy population density
rgely because of large population caused by
ss developed demographic status. Distinguished
rom them W.B., Kerala, Punjab, Haryana, Assam,
N, Jharkhand & Goa included in this category
eveals high carrying capacity, economic attractiveness
is the combined factors leading to high
opulation density.

Sparse Clustered Regions :=
These regions include all the states & UTs which
have population density less than the country's

Facebook Group: Indian Administrative Service (Raz Kr)

Facebook Group: Indian Administrative Service (Raz Kr)

average. It commonly includes unfavourable physiography & climatic regions which involves lesser carrying capacity. This category is represented by J&K, Sikkim, Nagaland, Manipur, Mizoram along with A&N Islands (46 persons/sq. km) and Arunachal Pradesh (17 persons/sq. km.) The analysis of sparse population in the case of 2 least densely clustered administrative units reveals that they are demographically backward with dominating 4th world communities with lesser population, thus, less popⁿ density. Distinguished from them Mizoram (52 persons/sq km) & Nagaland (11

reveals the examples of culturally & demographically developed regions of the country representing the cause of low population density.

Moderately Clustered Regions :-

In the moderately dense clustered regions with population density hanging near national avg rest of the administrative units are

Within this group, maximum

Facebook Group: Indian Administrative Service (Raz Kr)

Facebook Group: Indian Administrative Service (Raz Kr)

intra-regional disparity are highlighted which commonly depicts combination of extremely dense clustered & extremely sparse clustered areas within a state resulting in moderate density profile. As for example alluvial plains in A.P., Odisha, Chhattisgarh and Gujarat is more densely clustered compared to the plateau interiors. Similarly unfavourable climate makes W. Rajasthan significantly sparse with its popl^{n} compared to fertile chambal valley. For the states of Maharashtra & Karnataka clustered regions largely depicts urban industrial characteristics with Mumbai - Pune, Mangalore, - Bangalore industrial belts incorporating heavy population cluster. Unequal distribution of pop^{n} in India, therefore, reveals the combination of both natural and cultural factors.

Facebook Group: Indian Administrative Service (Raz Kr)

DEMOGRAPHIC DIVIDEND /REVOLUTION

Declining child population (0-6 years) which represents 13% of total population as per 2011 census combined with projected 65% of the total population share to be involving working age-group population by 2020-2 India is experiencing demographic dividends/revolution This revolution correlates to not just decreasing fertility and dependency ratio but also in the increase of female participation in the labour force. The experience of high-growth rate states as TN, Karnataka & Gujarat reveals that they incorporated lesser dependency ratio making it justify that the low growth rate states as Bihar, UP & MP is likely to benefit from continuous decreasing dependency ratio. Moreover cross country evidence suggest that productivity is an increasing function of age with 40-49 years of age being economically most productive because of the work experience. Population projections reveal that b/w 2011-2031, half of the addition in labour force will be in the age group of 30-49 making India

xpand her productive cohort whereas ever China
s registering consistent decline.

GENDER INEQUALITY & EMPOWERMENT (SEX RATIO)

The census data table combined with UN population table 2010-11 reveals that India makes the example of imbalance sex-ratio in the continuity of its consistent characteristics prevailing gender inequality in the country is also deciphered from the tentative index of human development called GII (Gender Inequality Index). As per the demographic data table India projects the examples of unfavourable sex-ratio recognised as historically -ve example of sex-ratio from among 10 most populous countries of the world The sex ratio trend however in past 3 census decade (1981-91, 1991-2001, 2001-2011) have shown consistent improvement with the present levels of 940 (940 females / 1000 males). This highest sex ratio since 1971 census when is compared with the 10 most populous countries of the world depicts it to be not just lower than

Facebook Group: Indian Administrative Service (Raz Kr)

global avg. of 984 but also one of the lowest among the comparable countries. It is only China (sex ratio :- 926) that represents poorer sex-ratio compared to India. Among the other countries Russia & Japan - consistent examples; with USA & Brazil representing sex ratio above equity.

INDIAN COMPARISION :

In the intra-national perspective 1951 census identified 11 administrative units with above equity sex-ratio. In accordance to 2011 census however it is only 2 administrative units - Kerala & Puducherry that reflects sex-ratio above equity. Reflecting the fact that economic development in the country is leading to the enlargement of gender inequality in terms of pattern peninsular states & union territories specifically Kerala TN AP Puducherry Lakshadweep & A&N Islands depicts sex ratio higher than country's level. In comparision extrapeninsular states have been the consistent low sex-ratio

depicting urals where in Haryana (877) have worst sex ratio among the states & among the UTs, Daman and Diu (618) females per 1000 males has registered lowest sex ratio. In the pattern of sex ratio most shocking data table has evolved in the case of child sex ratio (i.e. no. of girls, 0-6 yrs, per 1000 boys), the 2011 data table reveals it to be 914 i.e. lowest since 1971, with consistent decrease since 1971 census. It is at this level that non of the northern Indian states reveal child sex-ratio more than 900 with J&K the state depicting highest fall in child sex ratio in the last 10 years. The more prominent cause of concern however is favourable sex ratio depicting states as Kerala Maharashtra have also registered decline in the child sex ratio. Among the silver lining north Indian states have been depicting slight improvement and only NE^n states

the country welcoming the girl child.

GII

GII forms the composite index that is the measure of persisting inequality in the achievement b/w male and female popln in 3 distinctive dimensions:-

Reproductive health

Empowerment

Labour market

The data tables of reproductive health involves 2 distinctive dimensions called maternal mortality ratio and adolescent fertility rate. In terms of maternal mortality ratio (MRR) i.e. defined to be ratio of maternal deaths to the no. of live births given in a particular year, expressed as number per lakh live births. Indian MRR at 200 is one of the highest among the BRICS countries with China having MRR of 37 only.

The adolescent fertility rate is defined to be no. of births to the women in the age group of 15-19 per 1000 women of same age group. India depicts poorest stand among the BRICS

countries with upto 75 live births to the adolescent women justifying the depravation the young girls are subjected to in terms of education & economic empowerment. The comparable chinese figure is 9.

The index of empowerment involves the measurement of female representation in the national parliament along with population with at least secondary level of education. For the index of representation in the national parliament it is proportion of seats held by women that is taken into account expressed as %. Among the BRICS countries India represent poorest stand with ~11% of female representation with comparable figure of China being near 22%.

In the index of secondary education level it is percentage of population >25 years of age that have reached secondary education is taken into account. As per this index India depicts least levels of both male & female population

aching secondary level of education combined ith maxm gap b/w male & female - secondary lucation levels.

abour force participation rate : Willing to participate in work

ABOUR FORCE PARTICIPATION RATE :

It is defined to be proportion of country's working age popln that engages in labour market. It is expressed as percentage of working age population. Among the BRICS countries India depicting highest representation of male with least representation of female popln justifying prevailing gender inequality. Taking these parameters of inequality prevailing in the country, national policy for empowerment of women primarily focuses on

(a) Adolescent girls

(b) Maternal health

(c) Skill Development.

The adolescent girl programme called SABLA incorporates all round- development of girls in the age group of 11 – 18 years with components called nutrition & non- nutrition. The nutrition component entitles girl to take hot cooked meal with the distinction of 11 to 14 years, out of school girls and all girls between 14 to 18 years — This component involves resource - sharing b/w union & state governments (50:10). The non-nutrition component catering developmental needs of adolescent girls is cent percent union govt. sponsored. It involves the provisions of health and education counselling, vocational training apart from the supplies of food nutrition supplements.

With high maternal mortality ratio (MRR) this component of women empowerment involves the priority clauses of Janani

- Shishu Shuraksha Karyakaram that involves the objective of ensuring all the delivery in the health centres with complete expenses cleared by union govt.

- The Indira Gandhi Matritva Sahyog Yojaga which is the conditional cash transfer scheme sponsored by union govt. to facilitate part compensation of wage lost & improve health status of mother & child. Maximum of 4000 rupees provided for first 2 live births for women >19 years of age.

- Integrated Child Development Scheme (ICDS) the oldest scheme in the segment involves the holistic development of children upto 6 yrs of age is now supporting pregnant women & lactating mother also for their entire range of health & nutrition requirement.

SKILL DEVELOPMENT

It involves the support for training and employment program for women called STEP. Launched in mid-1980s it is decentralised skill development program on self-sustaining basic. Currently it includes skill development training in handloom, handicrafts, social forestary, traditional household & cottage industries, dairy culture, aqua-culture & wasteland development. Under this programme maxm. of 5 yrs. of training is provided with maxm. per capita cost of Rs 16000 with resource sharing b/w union govt. and implementing agency at (90:10) ratio.

LITERACY : INDIA

Literacy is defn. to be the ability to read write & understand. It involves 2 different measures called crude literacy rate & effective literacy rate. The crude literacy rate is the no. of literates divided by total popln expressed as %. whereas ELR is no. of literates 7+ years of age divided by total popln of 7+ yrs. expressed as %. Since 1981 census, ELR have been absolutely followed which marked its increase to 74%. (2011 census) from near 50% (1991 census). This improvement however is short of the target of

projected by planning commission for 11th five year plan of 85%. The pattern of literacy reveals that UTs & states with significant small proportion of countries popl^{n} as Kerala, Lakshadweep, Mizoram, NCT, Chandigarh have literacy rate >85%. Whereas the states with major popl^{n} share UP, Bihar, WB, A.P, M.P. & Rajasthan have literacy levels < 70%. Another characteristic of pattern called male-female literacy gap have been decreased in the country from >24% to less than 16% in the last census decade. However, the states like Rajasthan, Bihar, MP, Chhattisgarh & J&K reveals high gap of >20% in the male-female literacy levels.

MIGRATION

Spatial mobility of population is defined to be migration. This cultural functional variable as influences & geographical areas together it is related & stronger geographical characteristics than fertility and mortality. Migration distinguished from commuting and circulating movements involves change of residence for more than a weeks time. The causes of migration are distinguished as:

(a) Push Factor
(b) Pull

The push factor are operational at the place of origin. whereas the pull factor at the place of destination. Both these factor involves real or perceptional dimension as well. For migratory decisions, complicated intermix of distinctive factors highlights the importance of generalised migration theories propounded by human geographers. Among the most refered examples, Ravestein - Theories on Migration ; Everett Lee - Model on Migration, and Zelinsky - Mobility Transition Model, are included.

Ravestein took into analysis international migratory trends across north Atlantic in b/w 1885 to 1889. Based on these analysis he outlined some theories on migration including:

(i) Majority of migrants travel short distance (Distance Decay Effect)
(ii) Main cause of migration is economic
(iii) Adults migrate more than families.
(iv) Females migrate short distance whereas males venture beyond.
(v) Big towns grow on immigration
(vi) Every migratory current have weak & Opposite counter-current.

(vii)* Migration proceeds step-by-step

(viii) Every settlement have attractive field that is directly proportional to its size & inversely proportional to the square of distance (Gravity-Law).

Everett Lee: Model on Migration

This model involves consolidation of fragmented theories outlined by Ravestein. Lee emphasized that migratory decisions are regulated by four set of factors:

Factors operational at place of origin
" " " " " destination
Factors operating as intervening obstacles
Factors specific to individuals.

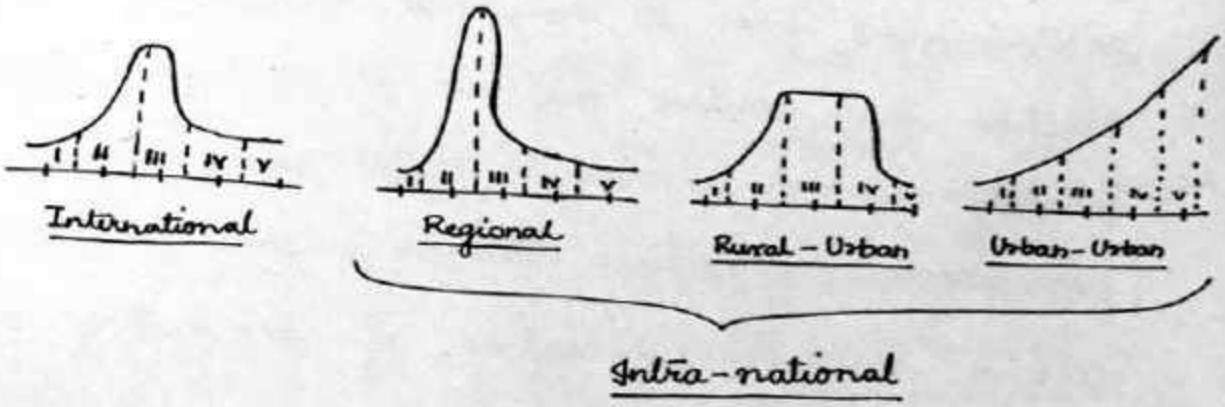

For the migratory decision to take place the factor operating in the place of destination is reqd. to be strong enough to <u>supress</u> place belongingness acting in place of origin <u>satisfying</u> individual requirement and <u>overcome</u> intervening obstacles. This consolidated migratory model with its open ended characteristics is applied for all the migratory decisions barring the exception of migrations caused by push factors.

ZELINSKY'S MOBILITY TRANSITION MODEL

In year 1971, Zelinsky attempted integration of migration in the demographic transition model. Identifying the influence of growth of population, cultural-economic advancements on migratory decisions, he analysed the transition in migratory movements at 4 variable scales :=

(i) International
(ii) Regional
(iii) Rural-Urban and
(iv) Urban-Urban

Facebook Group: Indian Administrative Service (Raz Kr)

Lecture # 56 Zelinsky's Mobility Transition Model Contd.

1/2014

International and Regional Migration

According to Zelinsky's Model, international and regional migrations represent highest level after expanding early stage. This is primarily due to increase in population as well as capacity of people to move from 1 location to other. Difference in volume is primarily attributed to involved distance in international and intra-national migration.

In international category, decline in migration in spite of growing popln is correlated to immigration norms that becomes more rigid with advancement of culture and modernisation.

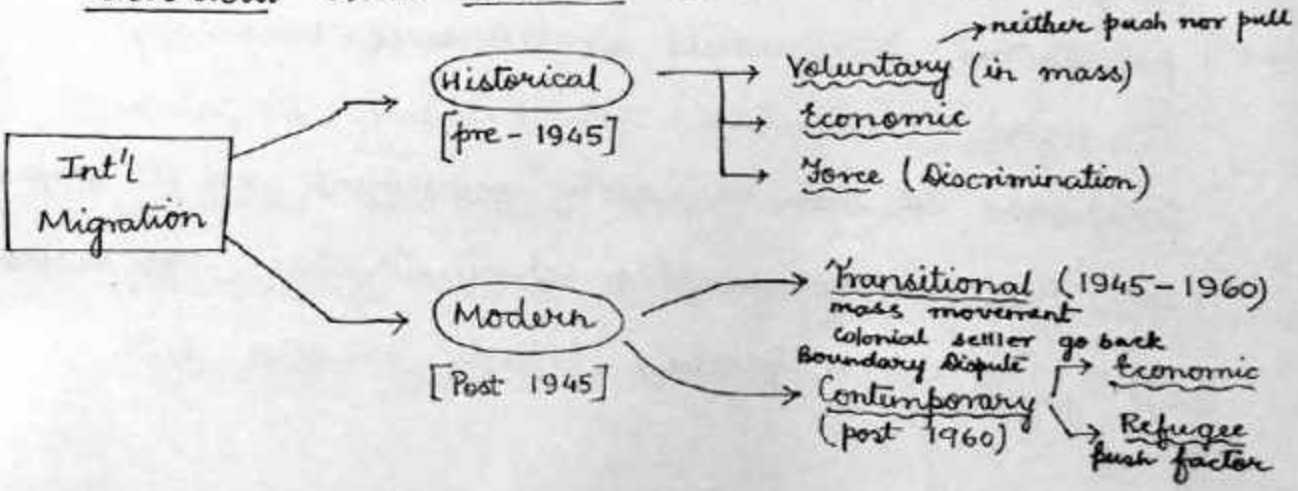

Distinguished from it regional migration register decline as positive outcome of regional development program, which minimises both real and perceptional difference between region at "rural urban scale". Continuation of dominating pace of migration for longer time period is due to delayed implementation of rural development,

Facebook Group: Indian Administrative Service (Raz Kr)

level of urban-urban migration depicted as special case of involves continuous rising trends as per functional capacity differences between different urban places. It is this difference that makes town dwellers always attracted to city & city dwellers to megacity. Significance of mobility transition model relates to the fact that this model helps in interpreting entire range of migratory movement in global and international level that have resulted in genesis of dominating cultural or economic identity of population.

The International Migration :

Since the beginning of cultural history it involves well demarcated temporal category interpreting practical significance of mobility transition model. Among the definite category of important trends, historical and modern are included.

Facebook Group: Indian Administrative Service (Raz Kr)

Historical Migration :
outlined for period of pre-1945, historical migration commonly incorporate mass movement of population across international boundary due to variable causes leading to variable consequences. Among migratory movement that have strong imprint on cultural demography and economic characteristics, voluntary, economic and forced migrations are included.

Voluntary migration : It involves movement of European Settlers, settling new worlds. In general absence of any clear push / pull factor, it is distinguished from other defined category. It is in legacy of this migration that caucasoid race dominates the map of world along with domination of Christianity and Indo-European linguistic family.

It is the voluntary migration that forms the cause of cascading economic development registered in Anglo-America and Oceania as with migrating population there was simultaneous technology transfer.

Compared to this migratory movement and its impact on human geographic characteristics, the economic and forced migration proves smaller but

Facebook Group: Indian Administrative Service (Raz Kr)

significant example.

ii) Economic Migration:

In this category, migration of industrial and agricultural labour are distinguished. In case of industrial labour, it was pull factor operational in Wn. European countries, generated due to Industrial Revolution that caused the migration. The source-region largely included Sn / En. Europe along with Nn. Africa.

It is this movement that represent to be the elementary cause of cosmopolitan cultural identity evolved in Western Europe.

In case of agricultural labour, it was tropical equitorial island induced with traditional plantation agriculture by colonial settler that evolved as destination. Trinidad & Tobago, Cuba - for cane plantation; Pemba Is., Mafia Is., Zanzibar Is. - for spices (clove) plantation; Sri Lanka (Tea); Malaysia (Rubber); Fiji (Mahogani) forms important examples. These islands attracted agricultural work force largely from neighbouring mainland depicting combined effect of Push

and Pull factor. It is this migratory movement that correlates to ethnic and cultural mix of these far off islands of the world.

1) Force Migration:

Relating to slave trade, this migration not just form one of the most inhuman and distinctive categories of mass migratory movement, it forms base of generated "racial discrimination" in global profile with dominating nature in caucosoid prominent region. Negroid population largely from Upper Guinea (West Africa), sold and purchased as commodities, were forced to migrate prominently in Anglo-America which forms base of genesis of black population in continent. Slaves were subjected to oppressive working and living conditions with prominent tasks performed by them like clearing of forest, levelling of land and facilitating development of condition required for basic infrastructure growth.

Modern Migration:

After 2nd World War, beginning of end of colonial regime and evaluation of most consolidated political map of world paved way to modern

migratory movements. These movements unlike historical counterpart not just involved greater travel distance but also correlated to more individualistic movement. Chronologically, this phase is sub-classified as tra itional and contemporary phases.

(i) Transitional Phase of Modern Migration :=

Roughly extensive between 1945-1960, this phase incorporate settling down of new evolving political map. ith the mass movement of population in commonest perspective this involve retreat of colonial settler. However, in terms of generated geo-political legacy such transitional movement correlates to geo-political sensitivity of south-Asia, geo-political sensitivity in East Asia as important examples. In both these locations, territory and boundary dispute forms the primary cause of fragile relation between neighbouring country with India - Pakistan and India - China as prominent-most example.

(ii) The Contemporary Phase (post 1960) :=

This phase primarily involves economic cause of movement with developing world being source-area

nd developed world being the destination. Being ndividualistic, these movement do not involve major ultural and economic imprint. During the decade of 980, economic commercial mobilisation of crude oil facilitated evolution of West Asia as important destination. These economic movement not just resulted in opening up of fundamentalist closed Islamic cultural identity of West Asia but also multiplied geo-political importance of this region. It is magnified geo-political interest that have been prime cause of political uncertainty, sectarial violence making region readily decline to as a favourable destination.

INTRANATIONAL MIGRATION :=

In contemporary intranational migration, erratic example of mass movement continues; regulated by push factor it generate movement of refugee. Turmoil in Arab world has been the most contemporary example of such mass movement. Such mass movement as analysed by UN Convention on refugee ~~security~~ justify that nine out of ten such movement of individual across the

Facebook Group: Indian Administrative Service (Raz Kr)

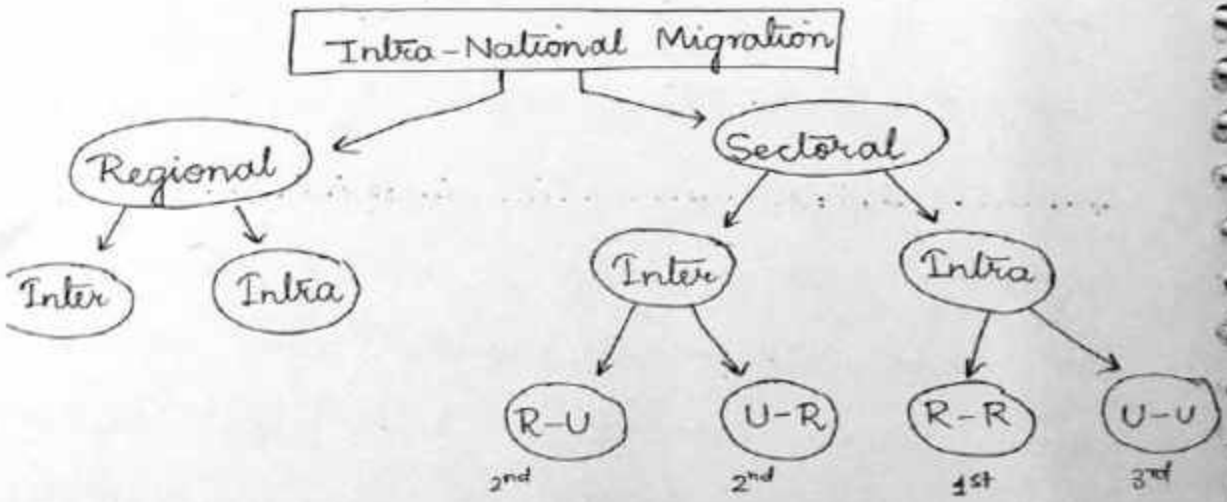

international boundary form illegal migration which continue to stay in the country, creating challenge on economic, demographic as well as security front. It is in continent of Africa that such mass movements are most consistent caused due to the reoccuring food ~~security~~ scarcity in SAHEL making people migrate to neighbouring food sufficient countries — Nigeria, Ghana as well as tribal conflict community in Savannah countries — Uganda, Rwanda, Burundi with Kenya, Tanzania acting as destination. Evaluation of youngest state on political map of world - South Sudan — have been additional cause of mass displacement of population across international boundary within continent.

INDIAN INTRA-NATIONAL MIGRATION :

Migratory data in India is derived from Census data table. Collection of migration data till 1961 census was in reference to "BIRTH PLACE". The 71' census added migration by last place of residence and it is since 81' census that causes of migratory decisions have been integrated in

Facebook Group: Indian Administrative Service (Raz Kr)

ollection of migration data. As the census data table akes into account gap of 10 year, minor migratory novement are overlooked that form the reason of ntegrating data collected by National Sample Survey rganisation to analyse migratory trends and pattern n combination of 2 data table, approximate 25% of country's population form 'MIGRATES' with rural dwellers showing more migratory tendency than other counterpart. In addition, main cause of migration in the country is ECONOMY. In between census decade of 2001-11, demarcated 'trends' of intra-national migration involves :

i) Rural - Rural :

Most dominating migratory movement identified in the country in last census decade is rural-rural migration. This intra-sectoral migration covelates to both intra-regional and inter-regional characteristics. In intra-regional perspective it involves larger migratory volume than inter-regional. Fundamental cause of this migratory trend is both perceptional and real disparity in agricultural development evolved in the country.

Movement between Awadh - Rohilkhand plateau interior to deltaic plain, and Marushthali to Banas Valley represent excellent example of intra-regional movement.

Distinguished from it, UP & Bihar as prominent source regions with Punjab, Haryana, Assam as prominent destination represent inter-regional migration of this category.

ii) Rural - Urban :

Second prominent migratory trend is Rural-Urban. This inter-sectoral migration have been most dominating migration since independence. It is

rigely regulated by push factor operational in rural area. Since 1981 Census, positive effect of "rural development program" have resulted in easing town of push factor making this trend slump to 2nd rank. This migratory movement primarily involves megacity as destination with rural dweller, primarily of population surplus states — U.P., Bihar, M.P. — acting as source areas.

Exponential increase in population and number of megacity in the country (million+) is primarily attributed to rural-urban migration. This migratory trend also include intra-regional & inter-regional sub-category wherein UP & Kerala make important example of intra-regional migration whereas Maharashtra, NCT, Chandigarh represent important destination for inter-regional rural-urban migration. Combined with urban-urban migration, exponential urban growth is experienced in the country.

(iii) Urban – Urban :

Unlike rural-urban migration, urban-urban migration involve all class category of urban area justifying functional capacity difference as cause of migration which has resulted in top-heavy pattern.

(iv) Urban – Rural :

The urban-rural migration is trace as it involves old age population migrating largely after the completion of their professional commitment. This migratory movement is technically referred to be COUNTER-CURRENT OF MIGRATION. Generated by these migratory trends, "Evolved Pattern" reveals :=

(i) UP & Bihar, population surplus states, with substantive high fertility levels form prominent source areas.

(ii) NCT & Maharashtra with substantive economic capacity combined with geographic and cultural proximity to sourced area form prominent destination

(iii) Most of the peninsular states represent example of stable areas in terms of their considerable distance from source regions

(iv) Unfavourable remote locations as Northern Mountain Wall, Great Indian Desert, Rann of Kuchchh forms example of isolated areas.

One of the prominent destinations for intra - national migration since independence — W.B. — failing to keep pace with required economic momentum is consistently declining in its attractiveness which is simultaneous to increase in agricultural attractiveness of Assam.
